Import and Export Data with readr

Introduction to R - Day 1

Instructor: Selina Baldauf

Freie Universität Berlin - Theoretical Ecology

The tidyverse

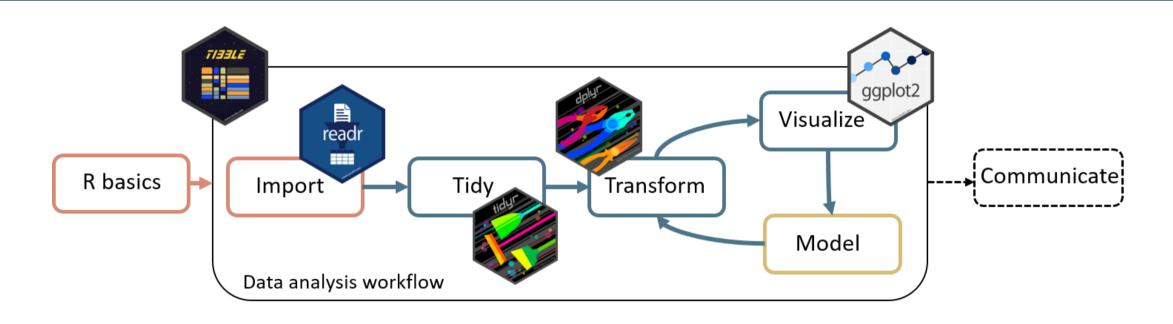

The tidyverse

The tidyverse is an opinonated **collection of R packages** designed for data science. All packages share an underlying design philosophy, grammar, and data structures. (www.tidyverse.org)

These are the main packages from the tidyverse that we will use:

Workflow data analysis

The tidyverse

Install the tidyverse once with:

```
install.packages("tidyverse")
```

Then load and attach the packages at the beginning of your script:

```
library(tidyverse)
```

You can also install and load the tidyverse packages individually, but since we will use so many of them together, it's easier to load and attach them together.

Import data with readr

Readr

readr is a tidyverse package. To use it, you can do one of the following things:

```
library(tidyverse) # or library(readr)
```

The most important functions are:

- read csv/write csv to read/write comma delimited files
- read_csv2/write_csv2 to read/write **semicolon delimited** files
- read tsv/write tsv to read/write tab delimited files
- read_delim/write_delim to read/write files with any delimiter

Read files with read *()

All read * functions take a path to the data file as a first argument:

```
read *(file = "path/to/your/file", ...)
```

Import files with a readr function fitting the delimiter of your file:

```
dat <- read_csv("./data/your_data.csv") # comma delimiter

dat <- read_csv2("./data/your_data.txt") # semicolon delimiter

dat <- read_tsv("./data/your_data.txt") # tab delimiter</pre>
```

Use read delim for a generic type of delimiter:

```
dat <- read_delim("./data/your_data.txt", delim = "\t") # tab delimiter

dat <- read_delim("./data/your_data.txt", delim = "..xyz..") # ..xyz.. delimiter</pre>
```

All read * functions return a tibble

Read files with read *()

Have a look at ?read delim for more options.

You can e.g.

- specify number of lines to skip reading with skip
- specify whether the data has a header column or not with col names = TRUE/FALSE
- change the data types of columns while reading them with col types

• ..

Write files with write *()

Every read * function has a corresponding write * function to export data from R.

Write data from R e.g.

- If tasks take a lot of time and you want to do them only once
 - Run the code, save the intermediate result, work with intermediate result
- To share transformed data

• ..

Write files with write_*()

All write * functions take the data to write as the first and the file to write to as the second argument:

```
write_*(x = dat, file = "path/to/save/file", ...)
```

```
write_csv(dat, file = "./data-clean/your_data.csv") # comma delimiter
write_csv2(dat, file = "./data-clean/your_data.txt") # semicolon delimiter
write_tsv(dat, file = "./data-clean/your_data.txt") # tab delimiter
```

Use write delim for a generic type of delimiter:

```
write_delim(dat, file = "./data/your_data.txt", delim = "\t") # tab delimiter
write_delim(dat, file = "./data/your_data.txt", delim = "..xyz..") # ..xyz.. delimiter
```

Absolute vs. relative paths

Absolute paths

```
C:/Users/Selina/some_folder/another_folder/data/file_to_read.csv
```

Relative paths

```
./data/file to read.csv
```

- relative paths are interpreted relative to the working directory
 - the ./ in the path stands for the working directory
- check out where your working directory is with getwd()
- in RStudio projects, the working directory is always the project root

Absolute vs. relative paths

Working with R and RStudio, the best way is to:

- Organize your work in an RStudio project
 - The project root is automatically the working directory
 - All your files are in one place
- Use paths relative to the project root

Why?

- no need to change the working directory
- portable paths: will also work on other machines that copied the project
- makes the code more readable
- less error prone

Some guidelines for data sets for **R**

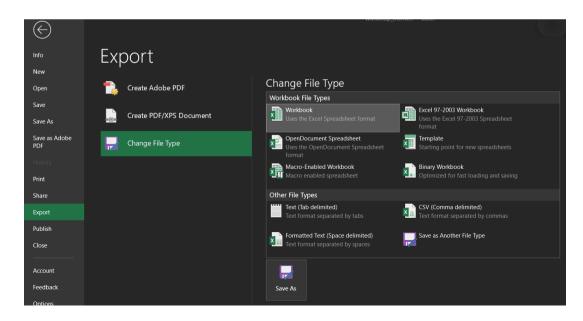

Data format

Follow these guidelines to make data import to R easier and less frustrating

• Readable file format: .csv, .txt & Co instead of .xlsx

Save an Excel spreadsheet as csv or txt either by

- 1. File -> Save As and select comma separated from the drop down menu
- 2. File -> Export

Data format

Follow these guidelines to make data import to R easier and less frustrating

- Readable file format: .csv, .txt & Co instead of .xlsx
- No white space in column headers
 - o use a character as separator, e.g. species name instead of species name
 - if this is unpractical, have a look at the function janitor::clean_names() from the janitor package
- Avoid special characters
 - o no ä, ö, ü, ß, é, ê, ...
- Avoid empty cells
 - o if you have missing values, put NA in the cell

Paths

- Avoid white space in paths
 - o data-raw/my data.csv instead of data raw/my data.csv
- Avoid special characters in paths
 - o no ä, ö, ü, ß, é, ê, ...

Now you

Task 4: Read and write data files (25 min)
